

MJ1410

8 BIT FORMAT CONVERTER

The MJ1410 is realised in N-channel MOS technology and operates from a single 5V supply. The circuit can be clocked from d.c. up to 2.5MHz and has 3-state output buffers capable of driving two LSTTL loads. All inputs are TTL compatible.

The MJ1410 performs the complementary functions of serial-to-parallel and parallel-to-serial data conversion on 8 bits of data. Both these conversions are achieved using the same time-position matrix, which has eight inputs and eight outputs.

An 8-bit parallel word clocked into the eight inputs appears as a serial 8-bit data stream on one of the eight outputs. Successive parallel words at the inputs appear as serial data streams on each of the eight outputs in turn.

Conversely, a serial 8-bit data stream on one of the eight inputs appears as an 8-bit parallel word on the eight outputs. Successive parallel words appearing at the eight outputs correspond to the serial data on each of the eight inputs in rotation.

The conversion can be 'programmed' to start in any register by setting the appropriate binary value on the counter pre-load inputs and applying a pulse to the Sync input. If the loading sequence produced by the counter is not required it can be disabled by connecting 'clock' to 'sync'. At each positive clock edge the register loaded will depend on the data on the counter inputs on the previous positive clock edge.
